Conclusions Gay men who report early FAI are at higher risk of HIV than those who report later FAI, and are more likely to have recently engaged in risky sexual behaviour. Discussion will focus on explaining these patterns and why health service providers need to pay attention to age at FAI.

**P2-S6.13 GAY MEN’S ASSESSMENT OF SEXUAL AND SOCIAL RISKS IN THE CONTEXT OF A RECENT HIV-POSITIVE DIAGNOSIS**

doi:10.1136/sextrans-2011-050108.365

**1Q Grace, 1M Kwag, 2M Steinberg, 2M Rekart, 1BC Centre for Disease Control, Simon Fraser University, Canada; 2BC Centre for Disease Control, University of British Columbia Canada**

**Background** Technological innovations in HIV testing that allow for the diagnosis of very recently-acquired HIV infections provide opportunities to understand sexual and social risk perceptions before and after an HIV-positive diagnosis. Longitudinal interviews with a group of gay men who have received an early or acute HIV diagnosis represent an important opportunity to understand risk assessment beyond individual-level paradigms of risk analysis and to broaden our understanding of social and structural risk factors associated with HIV infection, diagnosis and disclosure.

**Methods** Study recruitment is being conducted through six clinical sites in British Columbia, Canada (April 2009—December 2012) by the CIHR Team in the Study of Acute HIV Infection in Gay Men. Participants (n=12 at time of analysis) completed a series of self-administered questionnaires and semi-structured face-to-face interviews. Baseline qualitative interviews were recorded, transcribed verbatim and analysed. A thematic analysis, informed by a social organization of knowledge perspective, was conducted.

**Results** Three interrelated domains of risk assessment emerged from the interviews. First, we explicate how men calculated the epidemiological or sexual risks of transmitting HIV before and after their diagnosis and how such an assessment informed their sexual behaviours. Second, men described a myriad of experienced and perceived social risks, such as stigma and rejection, associated with their disclosure of their HIV-status to their family, friends, colleagues and intimate partners. Third, men identified potential problems with technologies of status notification which create a set of institutional risks related to the processes by which patients learn of their HIV-positive status. The relationship between these textually-mediated fields of risk is examined.

**Conclusion** A stratified conception of risk allows us to understand the everyday situations in which people assess HIV-related ‘dangers’ in their social and sexual lives. This formative research has important implications for educational campaigns on HIV transmission risk assessment for both HIV negative and positive gay men. This work can also inform counselling and support services to address how disclosure risks are negotiated during an early or acute HIV diagnosis. Important implications for clinical and public health practices, including how and when people are given their HIV diagnosis, are raised.

**P2-S6.15 INVESTIGATING THE CRITICAL PROGRAMME COMPONENTS OF HIV PREVENTION PROGRAMME AMONG MSM-TS IN BANGALORE, KARNATAKA**

doi:10.1136/sextrans-2011-050108.367

**R Prakash, S Isac, B M Ramesh, S Moses, R Washington, P Bhattacharjee, B Shetty, S Kumar. Karnataka Health Promotion Trust Bangalore, India**

**Background** A number of studies in the context of HIV/STI epidemic and related vulnerability have focused on the risk reduction of HIV/STI prevalence and condom use among female sex workers (FSWs). However, such studies focusing the men having sex with men (MSM) and transgender remains limited. Since the risk reduction of HIV/STI vulnerability among MSM-T is equally important, a systematic study is required to identify the critical programme indicators which increases the condom use and reduces HIV/STI prevalence among MSM-Ts.

**Methods** Two rounds of IBBA data collected from the urban parts of the Bangalore district are used. Bi-variate analysis is used to cross-classify the outcome measures by those who are exposed to the programme than those who are not, whereas the application of binary logistic regression analysis is done to get the adjusted effect of programme indicators on condom related outcomes (condom breakage in past 1 month, zero unprotected sex acts with commercial clients in past 1 month, condom use at last sex with communities in India. It is imperative to understand risk behaviour and vulnerable factors that lead to the spread of STI among communities. A study was undertaken to understand the sexual behaviour, vulnerabilities, among MSM attending STI clinic of the CBO at Kancheepuram District, Tamilnadu, India.

**Method** In the study 69 (72%) clinic attendees for a period of 9 months were followed up and interviewed at the STI clinic within the project. Consent and commitment was taken from the clinical attendees to be enrolled in the study. The project counsellor administered the questionnaire followed by clinical examination by the project Clinical provider.

**Results** Among the 69 MSM, 75.3% were 20–30 years & 11% were 31–40 years, 4.5% were above 50 years. Majority were from lower socioeconomic strata of the society and consisted of illiterate people also. 10% were uneducated, 27% Graduates and 44% had 5–10th grade education. About one-third (25.2 %) were married heterosexually, 65% reported travel to other states and 86% reported travel to other districts during the period of study. Among these 70% reported unprotected anal sex with casual partners during travel. Sexual behaviour: During the study period more than two-third (75.3%) had anal sex and all 69 MSM had oral sex. Condom usage, before and after counselling was 6% and 59.6% respectively. 15.9% had sex with female sex workers and 26% received money for sex. 43% MSM had sex only for pleasure and 52% have sex for both pleasure and money.

**Conclusion** It is imperative that the project develop specific programs like Partners meet or Lovers meet to introduce their partners to the project and thereby sensitise them on prevention of STI and increase condom use. Programs like “pre-departure counselling” about risks on unprotected casual encounters for MSM planning travel and “post-travel STI screening” should be attempted. Regular and periodic STI screening among MSM and partners may be implemented. This will help the project in addressing the risk of transmission of infections among the partners. Partners meet will be a platform for addressing greater Sexual behavioural issues beyond normative clinical interventions. Early diagnosis and Intervention of anal STI, regular Condom use and repeated Counselling are imperative to halt and reverse the STI epidemic among the MSM community.

**P2-S6.14 SEXUAL BEHAVIOUR, VULNERABILITIES AND CLINICAL INTERVENTION AMONG MEN WHO HAVE SEX WITH MEN (MSM) ATTENDING STI CLINIC; STUDY FROM SOUTH INDIA**

**1V S Prasad, 2S Shekhar. 1Strategic Partnerships, Chennai, India; 2Swarm, India**

**Introduction** Timely uptake of clinical services by highly mobile MSM is pre-requisite to halt and reverse STI prevalence among communities in India. It is imperative to understand risk behaviour and vulnerable factors that lead to the spread of STI among communities. A study was undertaken to understand the sexual behaviour, vulnerabilities, among MSM attending STI clinic of the CBO at Kancheepuram District, Tamilnadu, India.

**Method** In the study 69 (72%) clinic attendees for a period of 9 months were followed up and interviewed at the STI clinic within the project. Consent and commitment was taken from the clinical attendees to be enrolled in the study. The project counsellor administered the questionnaire followed by clinical examination by the project Clinical provider.

**Results** Among the 69 MSM, 75.3% were 20–30 years & 11% were 31–40 years, 4.5% were above 50 years. Majority were from lower socioeconomic strata of the society and consisted of illiterate people also. 10% were uneducated, 27% Graduates and 44% had 5–10th grade education. About one-third (25.2 %) were married heterosexually, 65% reported travel to other states and 86% reported travel to other districts during the period of study. Among these 70% reported unprotected anal sex with casual partners during travel. Sexual behaviour: During the study period more than two-third (75.3%) had anal sex and all 69 MSM had oral sex. Condom usage, before and after counselling was 6% and 59.6% respectively. 15.9% had sex with female sex workers and 26% received money for sex. 43% MSM had sex only for pleasure and 52% have sex for both pleasure and money.

**Conclusion** It is imperative that the project develop specific programs like Partners meet or Lovers meet to introduce their partners to the project and thereby sensitise them on prevention of STI and increase condom use. Programs like “pre-departure counselling” about risks on unprotected casual encounters for MSM planning travel and “post-travel STI screening” should be attempted. Regular and periodic STI screening among MSM and partners may be implemented. This will help the project in addressing the risk of transmission of infections among the partners. Partners meet will be a platform for addressing greater Sexual behavioural issues beyond normative clinical interventions. Early diagnosis and Intervention of anal STI, regular Condom use and repeated Counselling are imperative to halt and reverse the STI epidemic among the MSM community.
occasional clients/repeat partner/regular partner) and HIV/STI prevalence.

**Results** The sample includes 1452 MSM-T of which 56% belonged to the baseline while remaining to the follow-up survey. The mean age at sexual debut was lower and weekly client volume was higher among the MSM-Ts interviewed in the first round of survey which has shown a significant shift in positive direction in the second round of the survey. In context of programme exposure, higher percentage of MSM-T (about 75% vs 70%) reported project STI clinic visit, visit to DIC (68% vs 14%) than the baseline survey whereas the peer contact remained around 85% in both the rounds. The increased level of clinic/DIC visit found to be positively associated with higher proportion zero unprotected sex with commercial clients, consistent condom use with commercial clients/ repeat partner and with the regular partners in follow-up survey. The crude and adjusted OR shows a significantly less chances of HIV/STI among those who were contacted by peer (OR=0.78, 95% CI 0.67 to 0.99) and visited to clinic (0.82, 95% CI 0.79 to 0.96) compared to their respective counterparts after adjusting the effects of other confounders in the two rounds of the survey. The prevalence was significantly lower among those MSM-T who used condom with different type of partners at different occasions.

**Conclusions** The extent of peer-led outreach remain more or less over the period of time, however, a significant improvement in clinic/DIC visit found as the critical component in reducing the HIV/STI prevalence through increased means of condom use with different types of partners.

**[P2-S7.01] CONDOM USE AND THE DISPOSITION TO IT AMONG HIV POSITIVE WOMEN ACCESSING CARE AT AN ANTIRETROVIRAL CLINIC IN IBADAN, NIGERIA**

doi:10.1136/sextrans-2011-050108.368

1A O Adefolarin, 0 S Anulogun, 1F A Adeleke, 1AIDS Prevention Initiative In Nigeria Plus, Ibadan, Nigeria; 2Faculty of Public Health, University of Ibadan, Ibadan, Nigeria

**Background** Condom use remains one of the ways to prevent sexual transmission of HIV. However, its use among women living with HIV has not been well documented in Nigeria. This study therefore documented the use of condom among women living with HIV attending an ARV clinic in Ibadan, Nigeria.

**Method** This descriptive study was carried out among 396 consenting HIV positive women selected using a systematic random sampling technique in President Emergency Program For AIDS Relief clinic Ibadan. Data was collected using validated interviewer administered questionnaire and analysed using descriptive and χ² statistics.

**Result** The mean age of the participants was 34.8±9.0 years, 62.6% were currently married. 96 (24.2%) 15.2% were never married and 66.2% had disclosed their status to their partners. Three hundred and fourteen (79.8%) of the respondents reportedly were sexually active, of these 134 (42.7%) reportedly use condom in all sexual intercourse with their partners while 28.0% never used at all. A significant relationship was found between condom use and serostatus disclosure (p<0.05). Reported experiences among the 226 (72.0%) who use condom included endurance 115 (50.9%), enjoyment (39.8%), complaint 12 (5.5%), fed up (2.2%) and annoyance (1.8%).

**Conclusion** Condom use is prevalent among the study group and not many derived enjoyment from it, therefore health promotion strategies such as individual psychotherapy, health education on proper use of condom and provision of free varieties of condoms should be put in place to encourage its use.
